54 Secured package integrity.

57 The package (21, 81) includes a body (23, 82) and a closure (25, 83, 85, 87, 89), and a readily breakable electrical oscillatory network (29, 51, 51a) sans power supply is physically connected between the body (23, 83) and the closure (25, 83, 85, 87, 89). The network (29, 51, 53) is tuned to resonate at a predetermined frequency. The package (21, 81) is monitored by a transmitter-receiver (103) when it is distributed to a customer. The transmitter (115) produces pulse signals in a carrier frequency band which overlaps the resonant frequency of the network (29, 51, 51a). During monitoring the package (21, 81) is placed in the field of the transmitter (115) and the oscillatory network (29, 51, 51a) is excited to produce a decaying pulse for each transmitter pulse (119). If the package (21, 81) is sealed, the oscillatory network (29, 51, 51a) is intact decaying pulses are received to produce visual or audible signals. If the package (21, 81) has been opened, the network (29, 51, 51a) is broken and no signals are produced.

FIG. 1

EP 0 329 960 A2

SECURED PACKAGE INTEGRITY

This invention relates to the art of packaging and it has particular relationship to determining if a package which is assumed to be intact has been undesirably opened. This invention is applicable not only to bottles and boxes such as are used in the food, beverage and pharmaceutical industries, but, also, to sealed documents which may be classified or valuable. The word "package", as used in this application, includes within its meaning not only bottles and boxes, but, also, sealed documents.

Sharpe, U.S. 4,398,089, is typical of the prior art. Sharpe discloses a container including a radiation shell shielded from radiation detectors by a shielding shell. Sharpe states that when the container is broken, the shielding shell is ruptured and the detector picks up the radiation actuating an alarm. This expedient involves the hazards of radioactivity. In addition, Sharpe does not describe what its radiation material is and what kind of radiation it emits. Gamma radiation would require a heavy lead shield. An alpha radiation emitter such as Pu238 also emits gamma rays. The gamma rays would be present inside and outside of the container and would require shielding.

It is an object of this invention to overcome the disadvantages of the prior art and to provide for monitoring the integrity of packages without relying on radiation material.

In accordance with this invention, an electrical oscillatory network, i.e., a tuned resonant network, without a power supply is connected between the closure of a package or container and the body of a package. The network typically includes a one-turn spiral of conducting material overlapping at the inner and outer ends. This structure forms a one-turn inductance having a capacitance by reason of the overlapping ends, in parallel with the inductance, i.e., a parallel tuned network. The one-turn spiral is printed, by the methods of producing printed circuit boards, on a film of insulating material. The film seals the opening of the container. A dab of uncured adhesive is adhered to a region of the spiral. When the package is closed by the closure, the dab is engaged by the inner surface of the closure. After the adhesive is cured, the closure cannot be opened without tearing the electrically conducting spiral where the dab is adhered. The oscillatory network is thus broken.

The use of a multi-turn spiral is also within the scope of equivalents of this invention. In this case, the capacitance is formed between the innermost and outermost turns. The intervening turns serve, in effect, to reduce the dielectric distance between the innermost and outermost turns which has the effect of increasing the capacitance.

The package is monitored by a transmitter-receiver, typically under the counter over which the package is passed when purchased by a customer. The transmitter emits oscillation over a frequency band including the resonant frequency of the network. These oscillations are modulated by pulses. On the counter the electrical oscillatory network is in the field of the oscillations emitted by the transmitter. The oscillations are impressed on the network at the pulse intervals, each pulse transmitting energy to the network, exciting the network to emit a decaying pulse. After the transmission of the pulse ceases, the induced oscillations in the oscillatory network decay because of energy losses resulting from the network resistance and from electromagnetic radiation. Since the oscillatory network has a high Q, the decaying oscillations persist for an appreciable interval and can be detected. For intact packages, the receiver produces a signal corresponding to the received pulse during the interval between transmitted pulses. Typically, the signal may be an audio signal corresponding to the pulse rate. If the package is opened and the oscillatory network has been broken, then no signal is produced, indicating that the package is not intact.

For a better understanding of this invention, as described in the claims, reference is made to the following description taken in connection with the accompanying drawings, in which:

Figure 1 is an exploded view in isometric of apparatus embodying this invention and for practicing the method of this invention;

Fig. 2 is a partially diagrammatic view in isometric of an electrical oscillatory network assembly included in the apparatus shown in Fig. 1;

Fig. 3A is a partially diagrammatic view in isometric showing the first step in the formation of another electrical oscillatory network assembly;

Fig. 3B is a partially diagrammatic view in isometric showing a succeeding and final step in the formation of this other electrical oscillatory network assembly;

Fig. 4 is a generally diagrammatic view in isometric showing an embodiment and practice of this invention for monitoring the integrity of a package closed by flaps;

Fig. 5 is a schematic illustrating an electric oscillatory network used in the practice of this invention;

Figs. 6(a) and (b) together constitute a graph illustrating the operation of this invention; and

Figs. 7 and 8 are block diagrams for showing the manner in which a package is monitored in the practice of this invention.

The apparatus shown in Fig. 1 is a package 21 including a bottle 23 and a cap 25. The bottle is open at the top and includes an external thread 27 around its rim at the top. The thread 27 is engaged by mating internal thread along the lower rim of the cap 25. An electrical oscillatory network assembly 29 is interposed between the cap 25 and the bottle 23. The assembly 29 (Fig. 2) includes a film 31 of insulating material on which a one-turn spiral 33 of electrically conducting material is printed by a printed circuit process. The spiral 33 forms an inductance. The overlapping ends 35 and 37 of the spiral are insulated from each other and form a capacitance in parallel with the inductance. The spiral 33 and its overlapping ends 35-37 form an electrically oscillatory or parallel tuned network. It is desirable that the network 33-35-37 have a high Q and to achieve this purpose, the conductors forming the spiral 33 should be highly electrically conductive.

The film 31 is sealed to the rim 39 bounding the opening in the bottle 23 after the content of the container is deposited therein. A dab 41 of uncured adhesive is deposited at a region of the spiral and the immediately surrounding film. The cap 25 is then threaded onto the thread 27 closing the bottle 23. The dab 41 of adhesive extends above the film 31 to an elevation at which it adheres to the inner surface of the cap 25 when the cap is threaded onto the bottle. When thereafter the adhesive 41 is cured, the spiral 33 is adhered to the cap 25 so that removal of the cap breaks the tuned network.

Figs. 3A and 3B show another electrical oscillatory network assembly 50 in preliminary state and 51 in a finished state. This assembly includes a network 53 whose capacitance is higher than for the network shown in Figs. 1 and 2. As a first step illustrated in Fig. 3A, there is deposited on a film 55 of insulating material an electrically conducting configuration consisting of a loop 59 whose ends 61 and 63 overlap and are spaced a short distance from each other. The overlapping ends terminate in adjacent spaced conducting areas 65 and 66 which, preferably, are congruent. As a succeeding step (Fig. 3B), the film 55 is folded along a line 67 between the areas 65 and 66 substantially bisecting the space between them so that the area 65 under the fold 67 is aligned with the area 66 above the fold. The areas 65 and 66 and the film between them form a capacitor whose dielectric is the two layers of film. A dab 71 of uncured adhesive is deposited over the loop 59 and the immediately adjacent film for physically connecting to a closing part, such as the cap 25 or a flap, so that the network 53 is broken when the closing part is opened.

The apparatus shown in Fig. 4 includes a box 81 having a body 82 closed by overlapping inner and outer flaps 83 and 85 and 87 and 89 respectively at its opposite ends. An electrical oscillatory assembly 51 as shown in Fig. 3B is adhered to flap 83 and an assembly 51a to flap 87. After the box 81 is filled with its content, the flaps 85 and 89 are adhered to the dab 71. When the box 81 is opened at either end, the unfolding of the flap 85 or 89 breaks the network 53 or 53a adhered to the opposite flap 83 or 87. The networks 53 and 53a are tuned to different frequencies which can be distinguished readily. The difference may be effected by dimensioning the areas 65 and 66 (Figs. 3A, 3B) of network 53 differently than the same areas for network 53a.

Packages such as 21 (Fig. 1) or 81 (Fig. 4) are monitored as they are passed over the counter 101 (Fig. 7) where a purchase is processed. Under the top of the counter 101, there is a transmitter-receiver 103. The monitoring can be understood by consideration of Figs. 5 and 6. Fig. 5 shows schematically a parallel tuned network 111 which corresponds to the networks 33-35-37 (Figs. 1, 2) and 53 and 53a (Figs. 3B and 4). This network 111 includes a capacitance 113 and an inductance 114 connected by a conductor 112. As shown, the capacitor typically has a capacity C of 10^{-10} Farads and an inductance L of 10^{-6} Henrys. The resonant frequency is

$$\frac{1}{\sqrt{LC}} \quad \text{or} \quad \frac{1}{\sqrt{10^{-16}}} = 10^8 \text{ Hertz.}$$

For monitoring the package 21, the transmitter-receiver 103 includes a transmitter 115 which produces pulse modulated trains of oscillation 117 (Fig. 6a). The carrier oscillations are typically over a frequency band 10 peaking at 10^8 Hertz. Typically, the duty cycle of the pulses is 10% and the power output of the transmitter 115 is 0.1 milliwatt pulse power. For package 81, the transmitter 115 and receiver 119 are constructed to produce alternate pulse modulated oscillations whose carriers peak at the different frequencies to which networks 53 and 53a are tuned. This enables the monitoring simultaneously both ends of the package 81 to determine if the flaps 83-85 or 87-89 have been opened.

The package 21-81 is positioned typically about 1-foot from the transmitter 115 in the field of output of the transmitter. The receiver 119 is blocked during the transmitter pulse 117 (Fig. 6a) and is gated having a nominal threshold typically of 1 microwatt at 10^8 Hertz. On receiving a pulse from the transmitter 115, the capacitor 113 is charged and the network 33-35-37 or 53 or 53a is set into oscillation producing decaying oscillations 120 (Fig. 6b). The resulting omissions are received and detected by the receiver 119, following the interval during which each transmitter pulse is blocked, thus producing a train of decaying pulses 120 (Fig. 6b) having trailing ends. The trailing ends constitute a train of detectable emissions picked up by the receiver. The transmitter-receiver 103 includes an audio or visible indicator 123 (Fig. 8). If the package 21-81 is intact, the indicator 123 produces a signal corresponding to the train of detected emissions, if not, no signal is produced. This process may be reversed. The indicator may be set to produce a signal when a break is detected in the package 21-81. To prevent the indicator from producing signals between monitoring operations, the detector may be gated, for example, by a normally-open microswitch under the counter, which is closed by a package 21-81 when it is placed on the counter.

While preferred embodiments and preferred practice of this invention have been disclosed herein, many modifications thereof are feasible. This invention should not be restricted, except insofar as is necessitated by the spirit of the prior art.

Claims

1. A closed container (21, 81) including a body (23, 82) and a closure (25, 83, 85) for closing said body (23, 82) characterized by at least one electrical oscillatory network (29, 51, 51a) having no power supply including a capacitor (113) and an inductor (114), and means (41, 71) connecting said network (29, 51, 51a) at one region thereof to the internal surface of said closure (25, 83, 85) and at another region thereof to said body (23, 82) so that when said container (21, 81) is opened by removal of said closure (25, 83, 85) from said body (21, 81) said network (29) is broken.
2. The closed container of claim 1 wherein the container (21) is a bottle (23) having a body (23) sealed by a cap (25) characterized in that the oscillatory network (29) is connected to the cap (25) in one region thereof and to the body (23) in another region thereof.
3. The closed container of claim 1 wherein the container (81) is a package (81) having closures (83, 85, 87, 89) at each end including associated overlapping flaps (83, 85, 87, 89) including an outer flap (85, 89) and an inner flap (83, 87) having abutting surfaces when the container (81) is closed, characterized in that said container (81) including a pair of electrical oscillatory networks (51, 51a), each including a capacitor (113) and an inductor (114), and, means (71) connecting one network (51) to the abutting surfaces of the associated overlapping flaps (83 and 85, 87 and 89) at one end and the other network (51a) to the abutting surfaces of the associated flap at the other end so that on the opening of the outer flap (85, 87) at either end the network (51, 51a) is broken.
4. A container (21) having a body (23) having an opening and a cap (25) closing said opening characterized by a film (31) of electrically insulating material connected to said opening to seal said opening under said cap (25), an electrical oscillatory network (29) including a capacitor (113) and an inductor (114) secured to the outer surface of said film (31) and means (41) connecting said network (29) to the inner surface of said cap (25) so that on the removal of said cap (25) from said body (23) said network (29) is broken.
5. A container (81) having at opposite ends thereof each inner and outer flaps (83, 85, and 87, 89) for closing said container (81) characterized by a first and second electrically oscillatory network (51, 51a), each network including a film (55) of electrically insulating material having secured thereto a capacitor (113) and an inductor (114), means (71) securing said film (55) of said first network (51) to one of a first pair of surfaces consisting of the inner surface of said outer flap (85) and the outer surface of said inner flap (83) at one of said opposite ends means (71) connecting said first network (51) to the other of said first pair of surfaces, and means securing said film (55) of said second network (51a) to one of a second pair of surfaces consisting of the inner surface of the outer flap (89) and the outer surface of the inner flap (87) at the other of said opposite ends and means (71) connecting said second network (51a) to the other of said second pair of surfaces.
6. A method for electrically determining if a package (21, 81), having a closure (25, 83, 85, 87, 89) and a body (23, 82) closed by said closure, has been previously undesirably opened; characterized by the steps of producing a readily breakable electrical oscillatory network (29, 51, 51a) sans power supply, said network having a predetermined resonant frequency, securing said oscillatory network (29, 51, 51a) between said body (23, 82) and said closure (25, 83, 85, 87, 89) in such manner that opening of said closure (25, 83, 85,

87, 89) breaks said network, generating a signal having a frequency band overlapping the resonant frequency of said network (29, 51, 51a), positioning said package (21, 81) including said network (29, 51, 51a) in the field of said generated signal so that said network (29, 51, 51a) if intact, is set into oscillation by said signal, and monitoring the field of said oscillation to determine if said network (29, 51, 51a) is in
 5 oscillation thereby to determine if said package (21, 81) has been opened.

7. The method of claim 6, characterized in that the electrically oscillatory network (29, 51, 51a) includes an inductor (114) and a capacitor (113) and in producing the electrical oscillatory network said inductor (114) is formed by bowing a wire into a single-turn coil with the outer end and the inner end of the wire overlapping over a predetermined angle, and insulated from each other said inner and outer overlapping
 10 ends forming said capacitor (113).

8. The method of claim 6 characterized by the step of mounting the electrical oscillatory network (29, 51, 51a) on a thin film (31, 55) of electrically insulating material, sealing the container (21, 81) with said film (31, 55) and connecting the network (29, 51, 51a) to the closure (25, 83, 85, 87, 89) whereby the network (29, 51, 51a) is broken when the closure (25, 83, 85, 87, 89) is opened and the film (31, 55) is penetrated.

9. The method of claim 6 characterized in that the electrical oscillatory network (29, 51, 51a) is
 15 connected between the closure (25, 83, 85, 87, 89) and the body (23, 82) so that when the closure (25, 83, 85, 87, 89) is opened, the network (29, 51, 51a) is broken.

10. A method of providing a package (21, 81) having a body (23, 82) having an opening and a closure (25, 83, 85, 87, 89) for closing said opening with means for determining if said package has been
 20 undesirably opened, characterized by the steps of printing an electrical oscillatory network (29, 51, 51a) on a film (31, 55) of insulating material, sealing said opening with said film (31, 55) depositing a dab of uncured adhesive (41, 71) in contact with said network (29, 51, 51a), closing said opening with said closure (25, 83, 85, 87, 89) so that said dab is of adhesive (41, 71) is adhered to the inner surface of said closure (25, 83, 85, 87, 89), and permitting said adhesive (41, 71) to be cured whereby when said closure (25, 83, 85, 87, 89) is undesirably removed said dab of adhesive (41, 71) and a portion of said network (29, 51, 51a)
 25 adhered thereto are removed and said network (29, 51, 51a) is broken.

11. The container of claim 5 characterized in that the first and second oscillatory networks (51 and 51a) are tuned to distinguishably different frequencies.
